for iphone/ipod touch - 1.11GB. A third person shooter developed by 3D Realms. It takes place in the future, a la cyberpunk. The protagonist, John, is a Decker [...].The effect of adjuvant intravenous immunoglobulin on the immune response to intranasal influenza vaccination. Intravenous immunoglobulin (IVIG) is an effective treatment for patients with primary immune deficiency syndromes and in some patients with autoimmune diseases. In the present study, we investigated whether IVIG affects the immune response to intranasal influenza vaccination. Influenza virus vaccine was administered intranasally into patients with primary immune deficiency syndromes and mild to moderate allergic diseases. The effects of IVIG were examined in vitro and in vivo. Humoral and cell-mediated immune responses were assessed by enzyme-linked immunosorbent assay, in vitro cytokine production and lymphocyte proliferation. In vitro experiments showed that IVIG reduced the release of interferon-gamma, interleukin-4 and interleukin-6. In vivo experiments showed that the addition of IVIG to vaccine enhanced the intranasal immunization response. However, IVIG did not affect cell-mediated immunity. These results suggest that intranasal influenza vaccine may be enhanced by the addition of IVIG, and this may be useful in the treatment of patients who are considered to be at increased risk of influenza infection. Another milestone in the saga of the development of the Huntington's disease gene is in sight. With the publication of a paper last month in Nature, scientists demonstrated the ability to introduce the gene into human cells, resulting in the disease's hallmark neuropathology. The discovery paves the way for the development of therapeutics for the disease, as well as the study of the gene's function in humans. In the last decade, scientists have discovered that the gene responsible for Huntington's disease is located on chromosome 4. They've cloned it and found a mutation that causes the disease when it is present in a person's DNA. Now they've shown that, by inserting the gene into human cells that are the same type of cells present in the brain, they can cause the cells to reproduce the pathology of Huntington's disease. The findings are important because scientists can now manipulate the gene in cells before transplanting them back into the brain
